## Overview of the Proving Ground

The Hydrometeorological Prediction Center (HPC), the Ocean Prediction Center (OPC), and the Satellite Analysis Branch (SAB) of NESDIS will receive early exposure to GOES-R PG products from the end of 2011 through 2012. Pre-operational demonstrations of these GOES-R PG data will provide HPC, OPC, and SAB operational forecasters and analysts an opportunity to use, critique, and improve the GOES-R products so they can get a feel for the data that will be available after GOES-R is launched (~2015).

## Goals of the Proving Ground Project

Precipitation and QPF type products will be demonstrated and evaluated within the HPC, offshore thunderstorm and convective-type products will be demonstrated and evaluated within the OPC, and hazardous weather related products will be demonstrated and evaluated within the SAB. These products will be provided (near) real-time so the HPC, OPC, and SAB forecasters can use, get familiar with, and evaluate the products and provide valuable feedback to the GOES-R Program Office (GPO).

## Products to be Demonstrated

The GOES-R products to be demonstrated include those that use proxy Advanced Baseline Imager (ABI) and proxy Global Lightning Mapper (GLM) data. The initial products for 2011-2012 were chosen in consultation with HPC, OPC, and SAB based on their mission areas, areas of responsibility, feasibility, the similarity to planned GOES-R products, and forecaster availability for evaluation. These products are listed below:

- RGB Airmass – Decision Aid (HPC/OPC/SAB)
- Cloud and Moisture Imagery – Baseline (HPC/OPC/SAB)
- Lightning Detection – Baseline (OPC/SAB)
- Convective Initiation – Baseline (OPC)
- Enhanced “V” / Overshooting Top Detection – Baseline (OPC)
- Cloud Top Phase – Baseline (OPC)
- Cloud Top Height – Baseline (OPC)
- Cloud Top Temperature – Baseline (OPC)
- Volcanic Ash Detection and Height – Baseline (SAB)
- Rainfall / QPE – Baseline (HPC)
- Derived Motion Winds – Baseline (HPC/OPC)

## First Product to be Integrated into HPC/OPC/SAB Operations: The RGB Airmass Product

Figure 6

Figure 4

**Figure 6:** A MODIS Air Mass RGB of Irene prior to land-fall. MODIS helps to improve the color contrast within the RGB compared to the GOES Sounder due to the MODIS higher spatial and spectral resolution, and hence compliments the hourly imagery. (Image description courtesy of Kevin Fuell (NASA SPoRT))

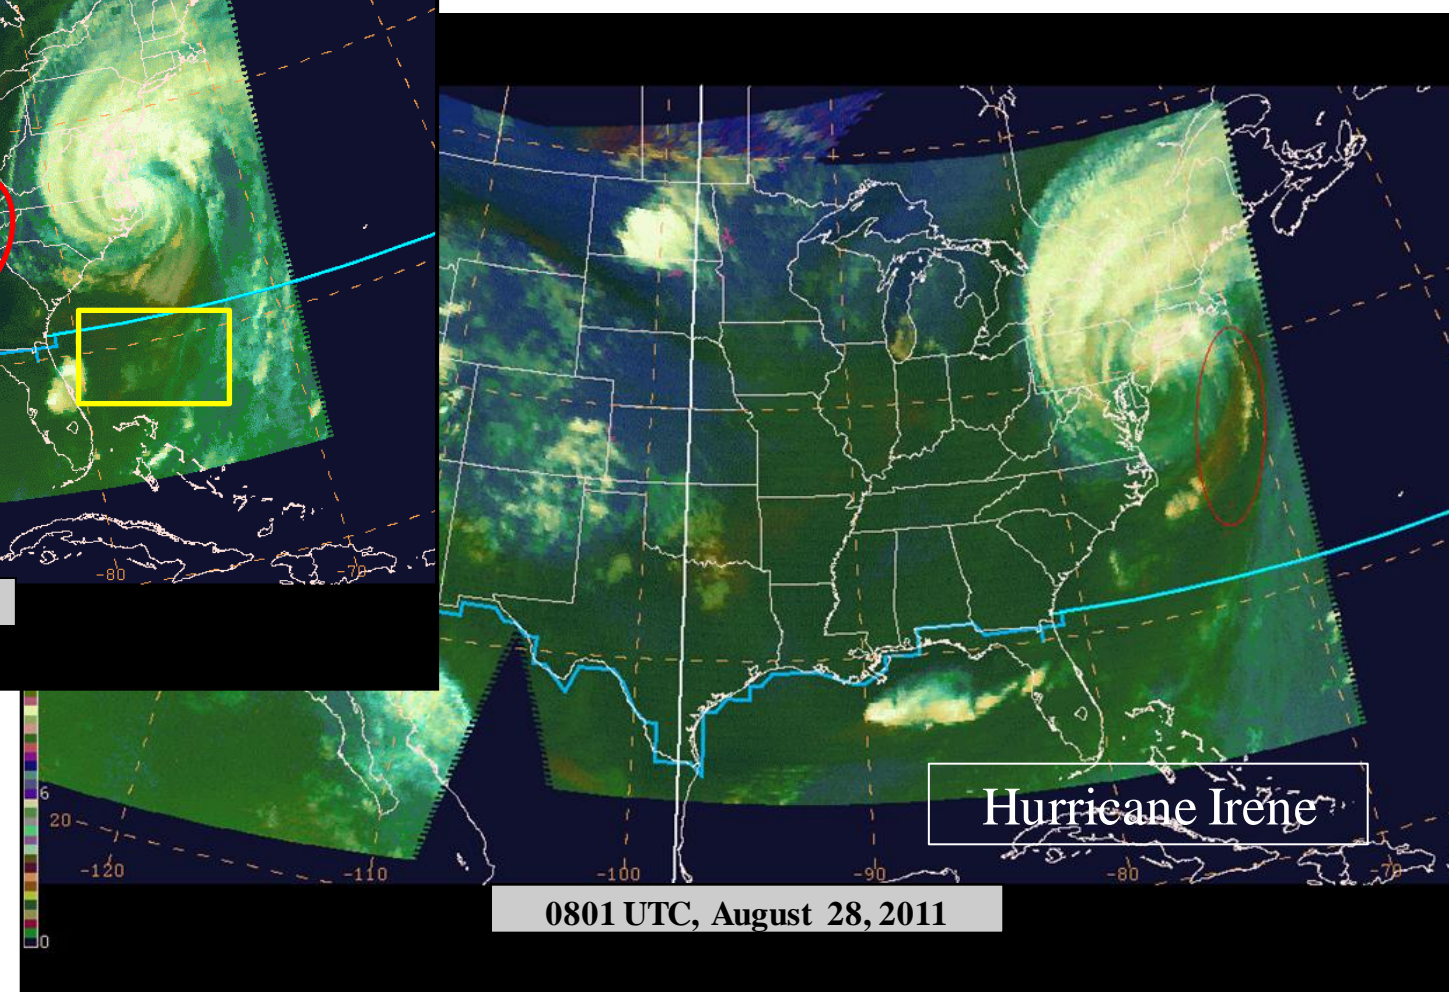

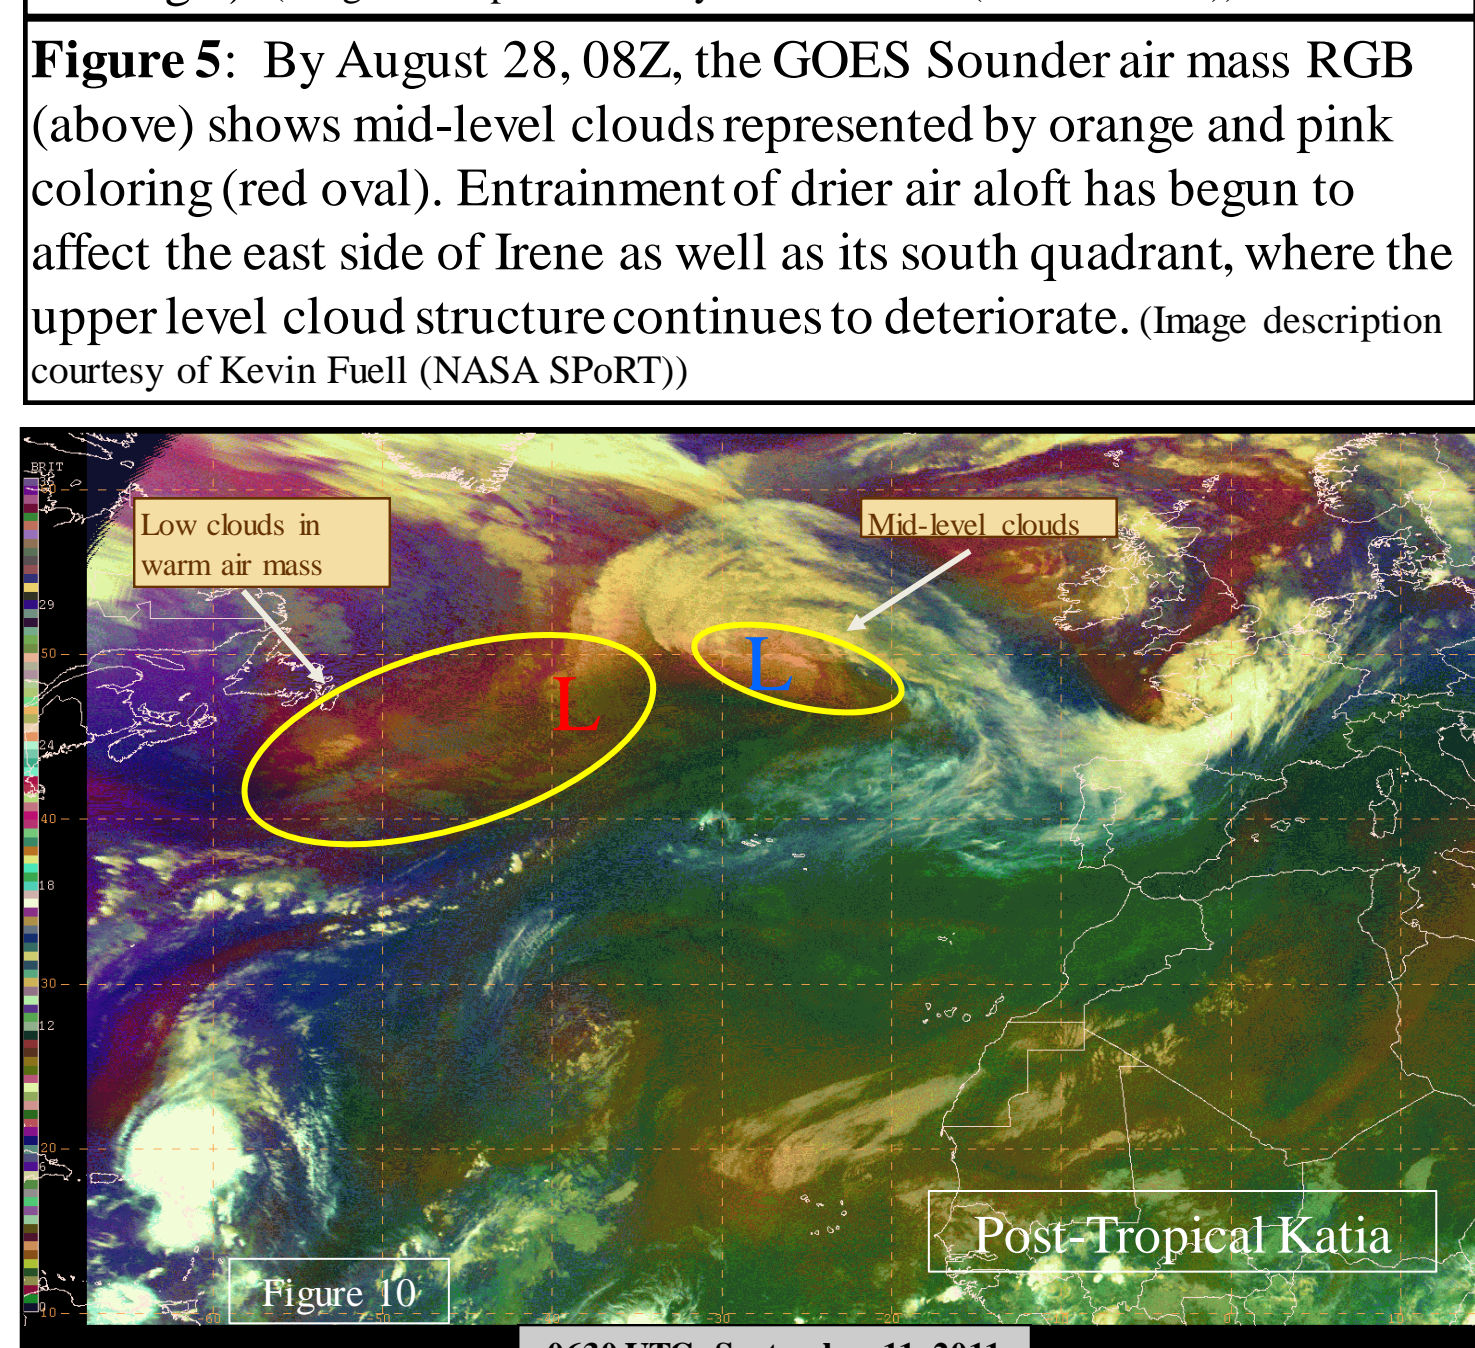

Figure 5

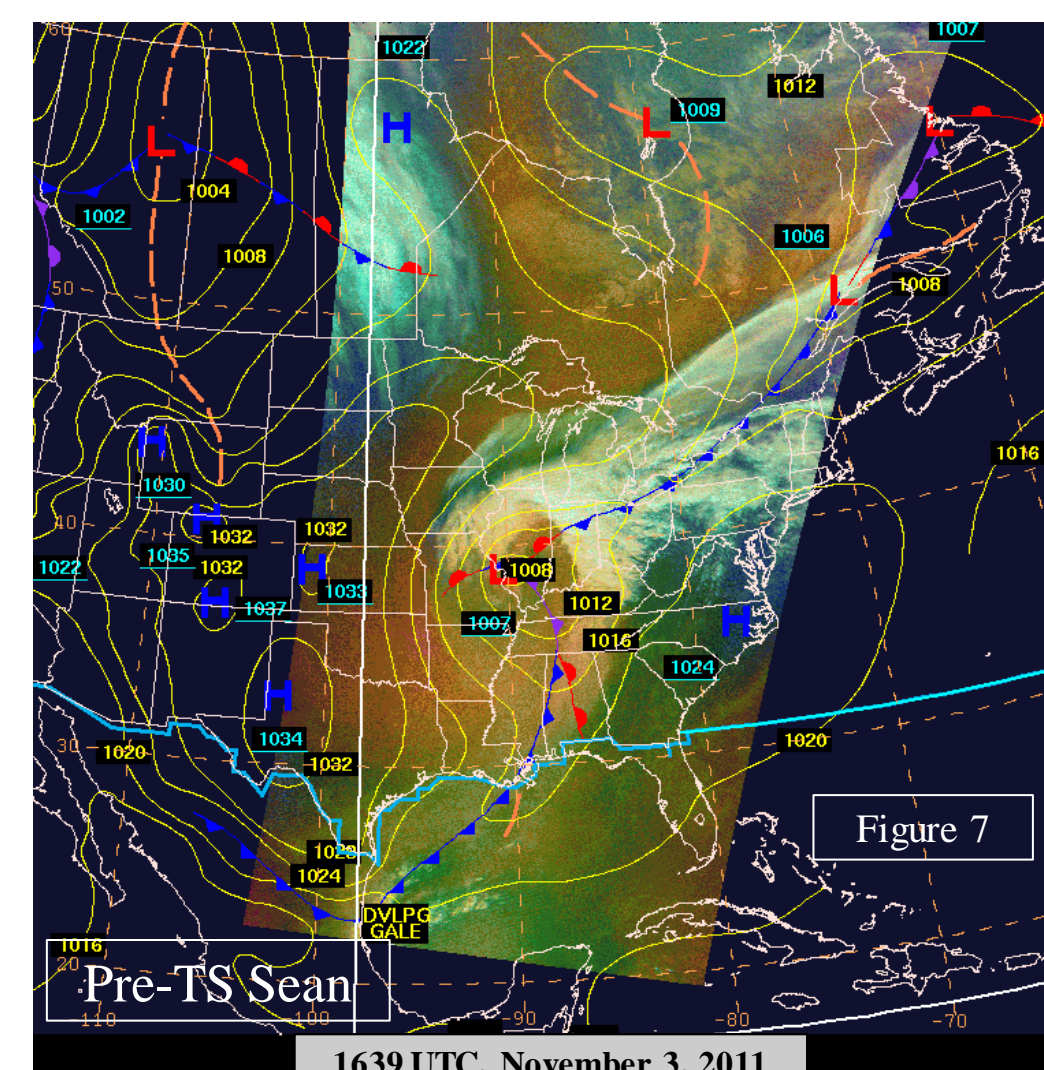

**Figure 4:** The GOES Sounder RGB Air Mass produced by John Knaff (NOAA/NESDIS/STAR) shows Hurricane Irene (2011) as it approached the NC Coast. The imagery shows that a cold front would intersect with Irene (blue line in MODIS image to left), which suggested an earlier-than-normal extratropical transition would occur. The GOES Sounder image at 20Z on 8/27 shows dry upper levels in an orange streak over OH and KY (red oval), but more importantly, the dry air mass behind the cold front is mixing into the south side of the storm. Out-flow of high-level clouds on the south side of Irene have been replaced by thick mid-level clouds as indicated by the RGB in light pink shades (yellow rectangle). (Image description courtesy of Kevin Fuell (NASA SPoRT))

**Figure 10:** Large field of mid/low clouds indicates dry air aloft is pushing well ahead of surface low.

**Details:** Katia's surface (red "L") and upper (blue "L") circulations have detached. The air mass RGB edges are falsely colored violet because of limb cooling and high O<sub>3</sub> absorption in the 9.7µm channel. However, Katia is far enough from the edges that OPC can see thick mid-level clouds (light pinks) near the upper low with thick low-level clouds in warm air (olive green) near the surface low, as extratropical transition rapidly continues. (Image description courtesy of Kevin Fuell (NASA SPoRT))

**Figure 9:** The MODIS RGB Airmass image shows TS Sean (NHC and SAB responsibility) at its peak intensity with an eye-like formation quite evident. The stratospheric air is still evident in the western and southern quadrants, but has diminished substantially from earlier imagery.

**Figure 7:** HPC is monitoring a storm pulling into the Ohio Valley after producing snow from CO into Kansas City. This was the precursor to Tropical Storm Sean (2011). The MODIS RGB Airmass imagery above shows an advection jet still evident cutting into the cyclone's center (yellow ellipse).

**Figure 8:** The MODIS RGB Airmass image shows the former snowstorm now northeast of the Bahamas with a very evident PV anomaly. OPC forecasters are now monitoring the system for Gale to Storm force winds.

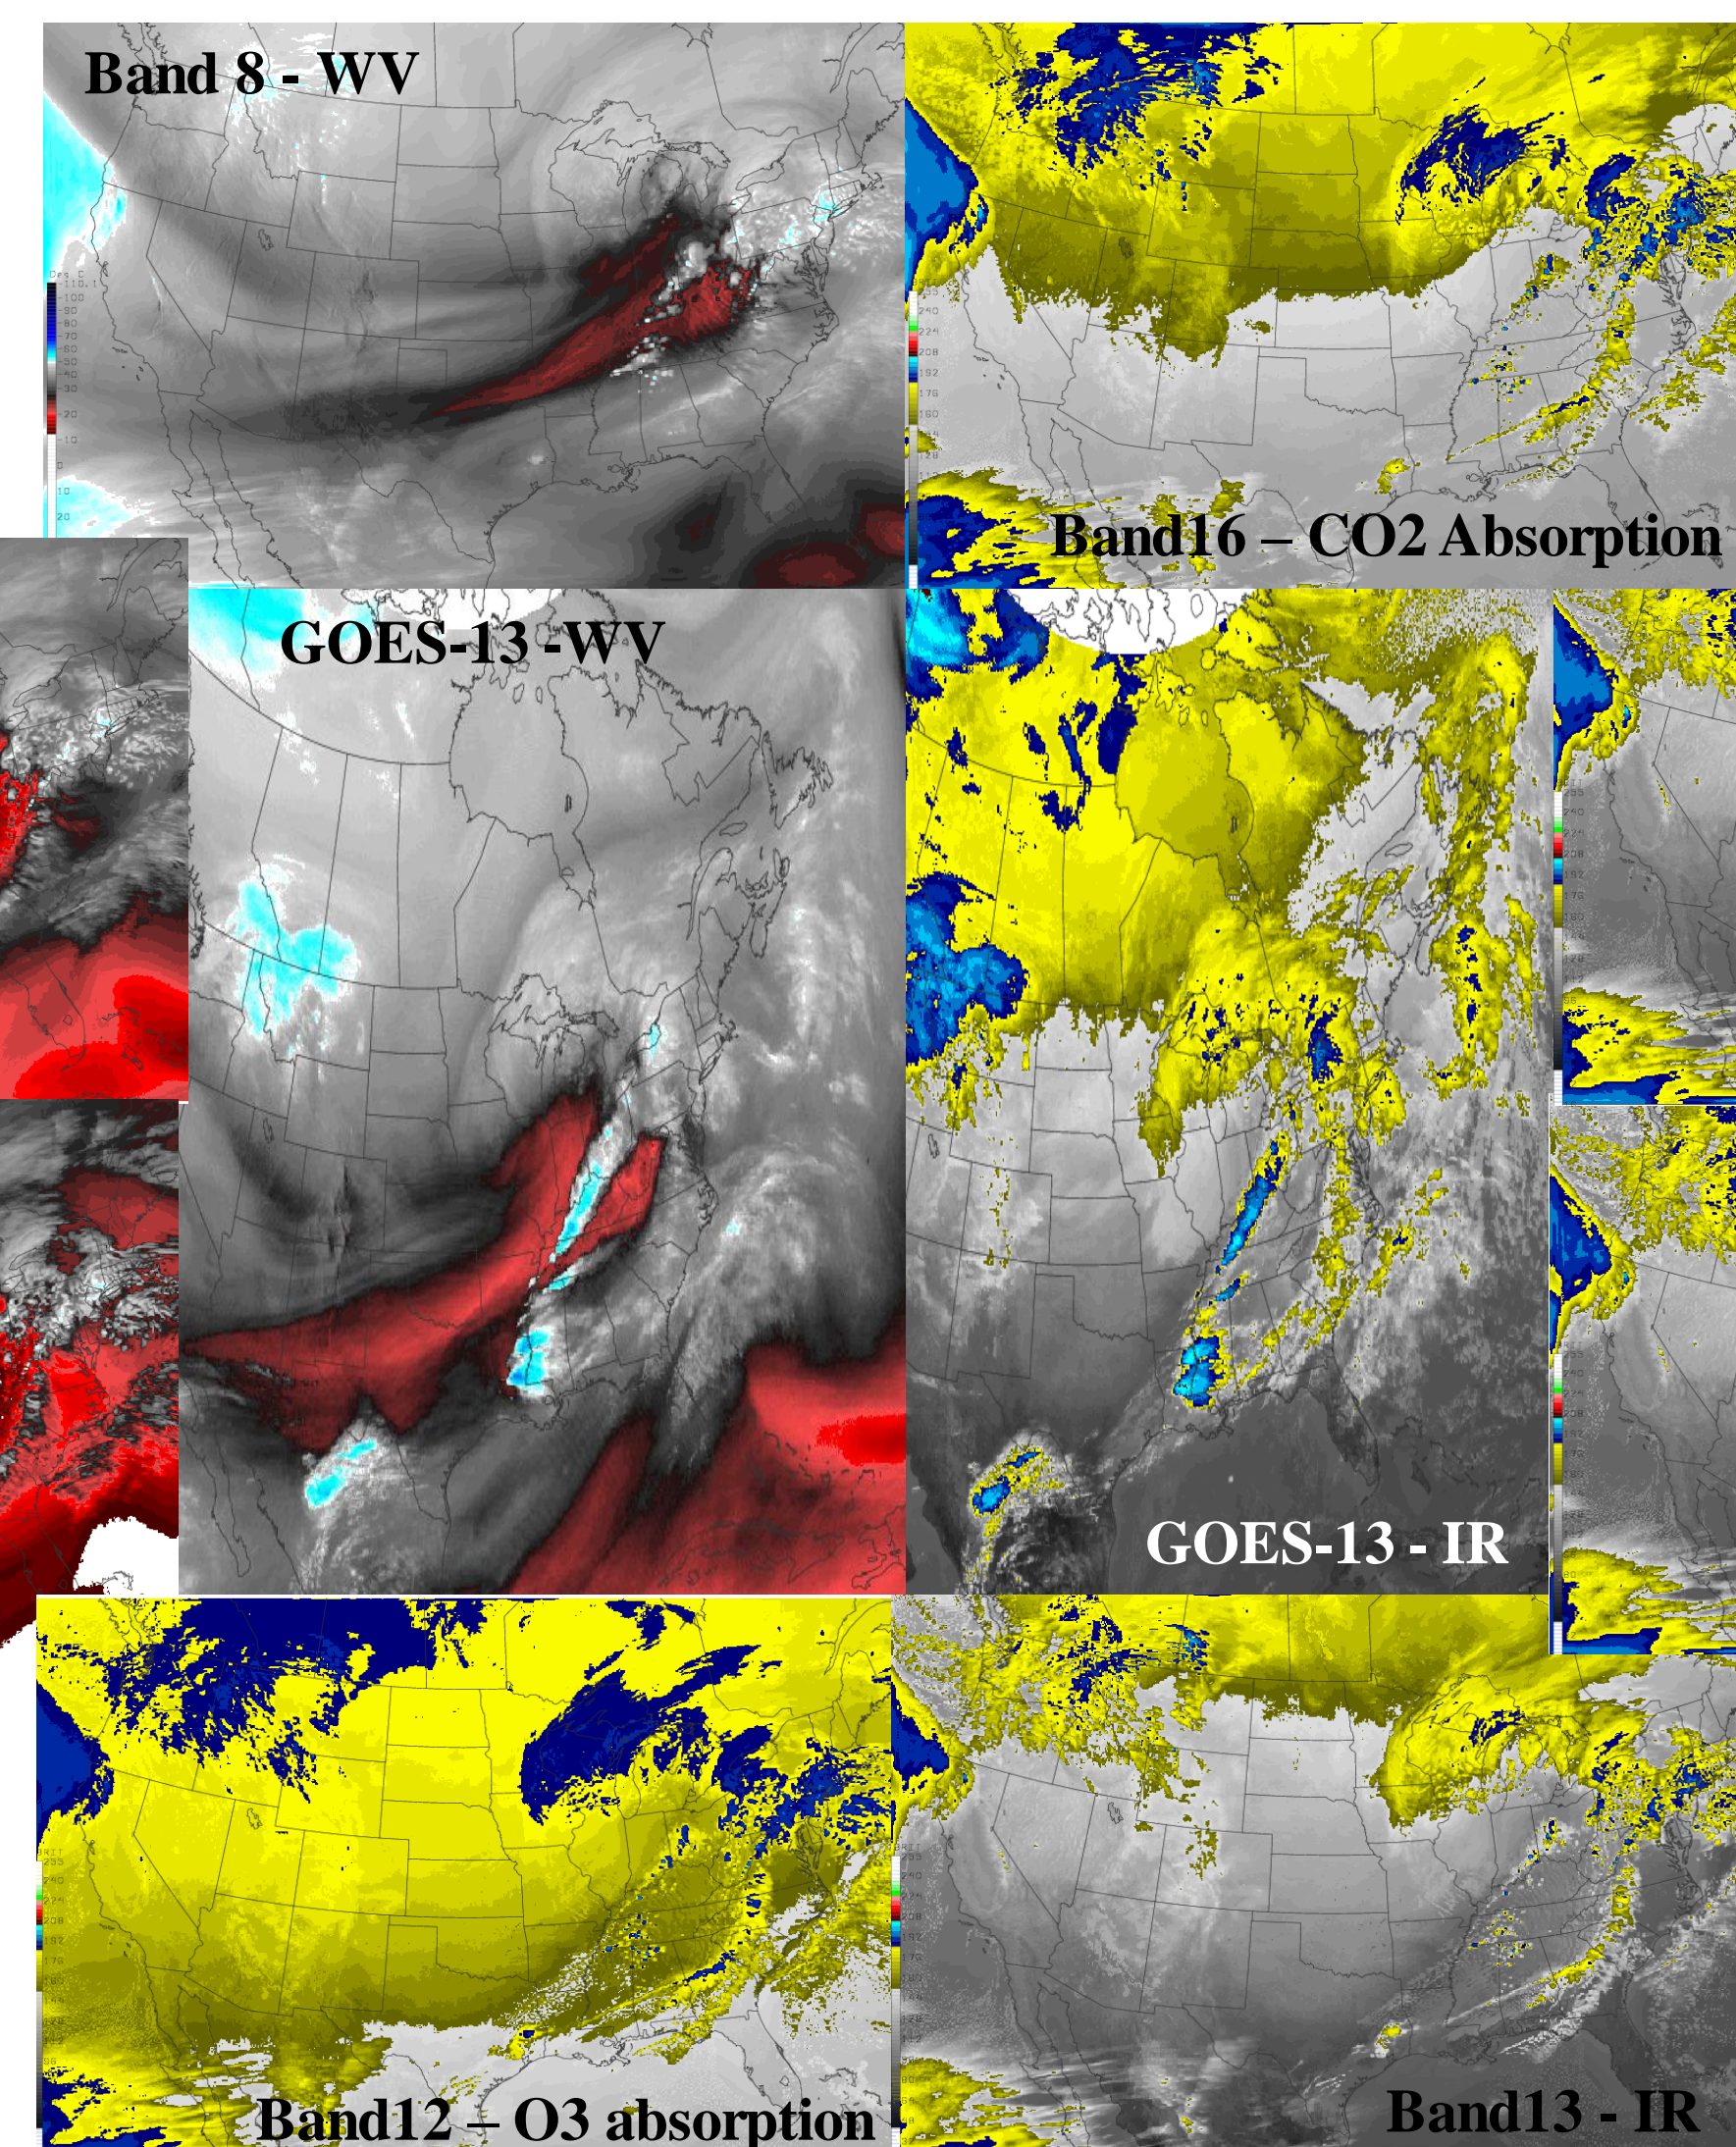

Figure 9

## Future Products to be Integrated into HPC/OPC/SAB Operations: WRF-simulated Advanced Baseline Imagery

## Enhanced “V” / OTD

The upper-left portion of the left image shows an enhanced-V producing storm over the Northern Plains in GOES-12 IR window channel imagery on 9 July 2009. The enhanced-V signature is outlined with a dashed line, the objective OT detection is shown with a blue circle, and the downstream warm region detection is shown with a green circle. (lower-left, left image) GOES-12 Visible channel image for the same scene. (right, left image) Severe weather reports from this storm. The image in the center shows two overshooting tops using the CIMSS OTD algorithm over the NC coastline. The image on the right shows the OT Magnitude algorithm identifying two strong cool season storms in northern MO and western IL.

## Proving Ground Vision for 2012

- Training on the RGB Airmass product is in full swing with evaluations slated to begin in February.
- Training on the Cloud and Moisture Imagery and Enhanced “V” / OTD products will begin late February and run through March with evaluations starting shortly thereafter.
- The goal is to have as much forecaster/analyst participation as possible so we can help incorporate these products into operations prior to the GOES-R launch.
- A training session involves using materials provided by the developers, then referencing current and past weather events to identify the usefulness to operations.
- Evaluations will involve feedback gathered in real-time operations along with a possible online survey to hit the developer's main prerogatives.
- Additional training material is provided where possible including COMET or VISIT modules.

## RGB Airmass Product used in Research at OPC

**Figure 1** shows the WRF-simulated 975 hPa theta gradient and **Figure 2** is the PBL maximum gust for a large extratropical cyclone in the North Atlantic from 01/31/11-02/02/11 (courtesy of Benjamin Albright (Howard U.) and Joseph Sienkiewicz (OPC)). **Figure 3** is the SEVIRI RGB Airmass product with an ASCAT wind pass overlaid to highlight the strong winds associated with the bent-back front feature (RGB imagery courtesy of Andrew Molthan (NASA SPoRT) with overlay produced by Joseph Sienkiewicz (OPC)). The WRF was able to reproduce this wind event to allow for further studying of the phenomena. The RGB Airmass image identifies the advection jet associated with a stratospheric intrusion wrapping in towards the cyclone center, thus identifying the PV anomaly.
